Resumen:

El objetivo de este trabajo es analizar en detalle la posición socio-económica de los indígenas en Chile, llenando, de esta forma, el relativo vacío existente en la literatura sobre la población aborigen en América Latina, que se ha centrado más en otros países con mayor porcentaje de población indígena. En primer lugar, se observa que tanto la pobreza extrema como la moderada son mucho más importantes entre la población indígena que en el resto de la población. En segundo término, la aplicación de medidas de pobreza no monetaria revelan unos resultados similares. No obstante, la polarización económica existente entre grupos étnicos es relativamente baja. Tercero, se han producido mejoras muy relevantes en las condiciones de vida de los indígenas durante el periodo de análisis, en la mayor parte de los casos mayores que las observadas entre la población no indígena. Por tanto, no puede sostenerse, a partir de nuestro análisis, que los indígenas chilenos hayan permanecido al margen de la prosperidad económica experimentada por el país en los últimos años.

Abstract:

The aim of this paper is to provide a comprehensive analysis of the socio-economic position of indigenous groups in Chile, filling an existing gap in the literature on indigenous population in Latin America, more focused on countries with a higher presence of aborigine population. First, it is found that both moderate and severe poverty are more acute among indigenous than among non-indigenous citizens. Second, these results also apply when using measures of non-monetary deprivation, like unsatisfied basic needs indicators. Nevertheless, income polarization by ethnicity is not high. Third, there have been large improvements in the living conditions of indigenous people, most of them even more substantial than among the rest of population. Therefore, it cannot be concluded that Chilean indigenous group have been marginalized from the remarkable economic prosperity experienced by the country during the last years.

Keywords:

Indigenous, poverty, unsatisfied basic needs, Chile.

I. Introduction¹

The times when ethnic issues were not a field of interest of Economics passed. In fact, together with the International Labour Organization remarkable encouragement for countries to recognize the rights of indigenous people in the late eighties, a huge effort has been made in the last years in order to explore the socio-economic situation of indigenous groups in several Latin American countries.² Particularly, among others, it is worth to mention the collective works of Patrinos and Psacharopoulos (1994), Hall and Patrinos (2005) and CEPAL (2006), which are devoted to study the economic disadvantages suffered by indigenous groups in Latin America, especially those related to health, labour market and human capital accumulation. Not by chance, those states where indigenous groups represent a larger share of total population (Bolivia, Ecuador, Peru, and Guatemala) are the cases most deeply analyzed, especially regarding earnings discrimination issues.³

The aim of this paper is to carry out a comprehensive analysis of the socio-economic position of indigenous group from 1996 to 2006 in Chile, a country that has enjoyed an enviable period of economic prosperity since the return to democracy in 1990.

In general, empirical research on Chilean indigenous people is scant. However, it is possible to mention several works devoted to these issues. For example, Valenzuela (2004) analyzes poverty among indigenous groups and inequalities in health and education using the *Encuesta de Caracterización Socioeconómica* (CASEN), the Chilean household survey, for 1996 and 2000; McEwan (2004) explores the explicative factors of the score test gap between indigenous and non-indigenous; Mideplan (2005a) offers descriptive statistics on indigenous exploiting the CASEN; and Sanderson (2006) constructs unsatisfied basic needs indicators using the Census 2002. Two recent works of Agostini, Brown and Roman (2008a and 2008b) try to compute poverty rates for each indigenous group imputing an income from household surveys for 2002 Census units, though its estimations limits to 2002 and monetary indicators and do not report any time trend.

¹ A very earlier draft of this work was presented at the 2007 Latin American Economic Association Annual Meeting in Bogotá (Colombia). Helpful comments from Rafael Muñoz de Bustillo and Vincenzo Di Mare are gratefully acknowledged. We also thank Chilean Ministry of Planning for providing us the databases used in the paper.

² “Convention concerning Indigenous and Tribal Peoples in Independent Countries”, General Conference of the ILO, Geneva, 1989. However, it should be mentioned that the ILO started to claim for the integration of ethnic and indigenous minorities in the middle of the past century.

³ Apart from the studies mentioned above, see, for instance, Villegas and Núñez (2005) on Bolivia, Gallardo (2006) on Ecuador and Ñopo, Saavedra and Torero (2007) on Peru.

The case of Chile seems particularly interesting, since this country has experienced the highest growth rate in the region for the last two decades, achieving unparalleled reductions of poverty. From 1990 to 2006, according to the Central Bank of Chile, GDP increased by more than 150% in real terms and, according to the Economic Commission for Latin America and the Caribbean (ECLAC), poverty incidence declined from almost 40% in 1990 to less than 15% in 2006. However, meanwhile, inequality remained high and stable. Therefore, it is interesting to explore to what extent indigenous people in this country has profit from such general economic prosperity. Furthermore, Chile is not included in the extensive and comparative World Bank studies of Patrinos and Psacharopoulos (1994) and Hall and Patrinos (2005), providing an additional justification for deepening in the Chilean case and fill this gap in the economic literature on indigenous groups in Latin America.

This article aims to go a step further than previous works, exploring the evolution of the deprivation among indigenous groups from 1996 to 2006, combining the analysis of incidence, intensity and severity of poverty and extreme poverty with the use of other measures related to basic needs. In order to accomplish these objectives, the paper is divided in five sections as follows. First, several details regarding the database and identification issues of indigenous population are provided. The second section presents the methodological tools used to study monetary and non-monetary deprivation. In the third place, results of the analysis of ethnic polarization and poverty and unsatisfied basic needs among indigenous population compared to non-indigenous are presented. The final section summarizes the main conclusions of the paper.

II. Database and Identification of Indigenous Groups

The data source used in this work come from the *Encuesta de Caracterización Socioeconómica* (hereafter, CASEN), a household survey carried out by the Chilean Ministry of Planning (Mideplan). It includes detailed data on income, dwelling and living conditions of indigenous and non-indigenous people for the 1996, 2000, 2003 and 2006 waves, which, consequently, are the only periods analysed here.

Patrinos and Layton (2005) straightforwardly show that it is not easy to quantify the presence of indigenous peoples in Latin America. For Latin America as a whole, these authors estimate a total indigenous population between 22 and 34 million. The reasons for such a lack of precision are the different possible approaches that can be used to count individuals as indigenous. Particularly, the three more common criteria in the region are language, self-identification and geographic concentration, with self-identification being the dominant approach in the last censuses and surveys.

The criterion used by CASEN for identifying indigenous population is self-identification. Particularly, the key question unfolds as follows: “*In Chile the law recognize the existence of 8 indigenous peoples. ¿Do you belong to one of them?*”. If the individual responds affirmatively he/she must point to which of the eight indigenous groups recognized in the *1993 Indigenous People Act* (aymara, rapa nui, quechua, mapuche, atacameño, colla, kawashkar, and yagán) belongs.

According to the CASEN 1996, 2000, 2003 and 2006 and the Census 2002, Chilean indigenous people represent roughly 5% of country total population, being the mapuches the largest indigenous group by far (since more than 8 out of 10 indigenous consider themselves belonging to the mapuche ethnic group).⁴ Unfortunately, the limited survey sample of indigenous and the small share of population represented by other indigenous

⁴ Those estimations are substantially different from those obtained from the Census 1992, where only those aged 14 and over were interviewed, and the self-identification question was related to the belonging to a culture (mapuche, aymara or rapa nui). The results obtained in 1992 are not comparable to later figures, because in 1992 a much larger part of the population declared to belong to the mapuche culture, a much broader concept than that of a people. The *1993 Indigenous People Act* established that a person belongs to an indigenous people if a person has an indigenous father or mother, if has an indigenous surname or maintains cultural features of the ethnic group. In addition, it is worth mentioning that the mapuches have often complaint about these figures and claim that they represents roughly 10% of the total population in Chile (see www.mapuche.cl).

people apart from mapuches, do not allow us to distinguish among the different ethnic groups in Chile in the analysis carried out here.

III. Methodological Issues

III.1. Poverty

The first step in measuring poverty risk is to define a set of indicators. Particularly, this paper makes use of the measures proposed by Foster, Greer and Thorbecke (1984), i.e., the FGT Index, which is defined as

$$P(\alpha; z) = \sum_{i=1}^N g_i(y; z)^\alpha$$

$$\text{where } g_i(y; z) = \max\left\{\frac{z - y_i}{z}, 0\right\} \text{ and } \alpha \geq 0$$

y_i denotes income of individual i and z represents the poverty line. g_i is the normalized poverty gap, that is, the income shortfall of each household or individual with respect to poverty line. α is a parameter that takes the value 0 for the Poverty Headcount (which measures the incidence of poverty); the value 1 for the Poverty Gap (which makes reference to the intensity of poverty) and the value 2 for the Squared Poverty Gap (related to the severity of poverty).

Finally, In order to measure monetary poverty, several methodological decisions related to empirics have to be taken. They are discussed below:

1. In relation to the definition of income we use only monetary income (including public transfers), excluding in-kind social expenditure (for instance, health or education subsidies).
2. Regarding equivalence scales, the analysis is carried out on a per capita basis, as the Economic Commission for Latin American and the Caribbean (ECLAC) and the Mideplan does.⁵
3. Both absolute and relative thresholds are used. First, we consider the indigence and poverty lines proposed by the ECLAC (and used by the Mideplan) for the period 1996-2006, which takes into account differences between rural and urban prices.

⁵ Other authors, like Contreras (1996) and Ferreira and Litchfield (1999), have proposed and used other equivalences of scales. We have carried out the analysis using other scales and results mostly hold. These results are available upon request.

The extreme poverty or destitution line is defined by the level of income required to achieve a consumption basket satisfying minimum food requirements. The value of poverty line is determined by increasing this budget in 75% in case of rural areas and 100% in case of urban ones (Mideplan, 2005b). Second, we also analyse how indigenous groups performs when we use a relative measure. Following the usual approach applied in OECD countries, 60% of median income is considered as the moderate poverty lines. Detailed information on poverty thresholds can be found at appendix I.

III.2. Unsatisfied Basic Needs

Although probably no economist questions the multi-dimensionality of poverty, how to account for this feature in the empirical analysis is far from being clear or well-established in the field. Here, we adopt an eminently pragmatic approach, using the Unsatisfied Basic Needs (UBN) methodology. First, it is an indicator widely used in Latin America, so it is familiar and, to a certain extent, transparent. Second, its information requirements can be fulfilled by our database. The application of the UBN methodology presented here heavily draws on the concrete proposal made by ECLAC (Feres y Mancero, 2001), which defines the main dimensions of basic needs and suggests a set of variables in order to implement this approach, and the work of Sana and Pantelides (1999), who applies the UBN method to Argentina. Basically, the methodology consists in, first, selecting a group of variables related to housing, access to water and sewerage facilities, children's school attendance and the economic capacity of households; second, defining a threshold for each indicator; third, considering a need as unsatisfied when a particular indicator is below the minimum standards defined by the researcher. If there is any unsatisfied need in a given household, it is classified as a household with UBN (and an individual have UBN when he lives in a household with UBN). In other words, it is possible to define a UBN index that takes the value 0 if there is no UBN and the value 1 in other case. The specific criteria followed here comprised four dimensions: dwelling, water supply and sewerage facilities, children education and subsistence capacity. The particular variables selected and the conditions under basic needs corresponding to each dimension are considered unsatisfied are described below:

- A. *Dwelling quality.* A household presents an UBN in this dimension if any of the following two conditions are verified:

- A.1. Housing quality. The household does not live in a house or a flat or dwelling is in bad condition -according to the definition proposed by Mideplan (2005b)-, which depends on the quality and condition of materials.
- A.2. Crowding. There are more than three people per bedroom.
- B. *Water and sewerage*. A household is considered to have an UBN related to this aspect if we observe one of the two following features:
- B.1. Dwelling is not connected to public water network.
- B.2. Dwelling lacks of adequate toilet facilities, that is, connected to public sewer system.
- C. *Children education*. This UBN is conditioned on the presence of children between 6 and 12 years old not attending school.
- D. *Subsistence capacity*. This dimension is analysed on the basis of an indicator of economic dependency of household proposed by the National Institute of Statistics and Censuses of Argentina (INDEC, 1998). For each household h , this indicator is defined as

$$SC_h = \frac{1}{n_h} \sum_{i \in h} s_i w_i$$

where s denotes the years of schooling of each individual living in household h ; w is a weight equal to 1 if the person is employed, 0.75 if he/she is a pensioner and 0 otherwise and n_h is household size. In words, each individual in our society is characterised by an income and, in order to compute the dependency ratio, we only calculate the sum of number of employed (or pensioned) members weighting by their educational level over each household; a sum then divided by household size. Mario, Gómez and De Oliveira (2004), who use this indicator to analyse economic capacity of households in Argentina and Brazil, establish several thresholds for this measure. Particularly, if SC is between 0 and 1.5, a household is considered to have a low subsistence capacity. Here, we apply this cut-off point, that is, an individual will present an UBN in this dimension if his/her household shows a SC not higher than 1.5.

Furthermore, following ECLAC methodology (Feres and Mancero, 2001), construction of UBN indicators can be combined with poverty lines methods, obtaining bi-dimensional or combined measures of deprivation.⁶ According to this methodology, households can be classified in four groups. Firstly, poor households (that is, those with per capita -or equivalent- income below poverty line) with UBN are considered to live in chronic poverty. In the second place, people living in poor households with no UBN are classified as situational poor individuals. Thirdly, the concept of structural poverty is applied to non-poor households with UBN, and, finally, non-poor households with no UBN are classified as socially integrated ones (see Table 1).

Table 1. Combination of poverty lines and UBN methods

	Households with UBN	Households without UBN
Poor households	<i>Chronic poverty</i>	<i>Situational poverty</i>
Non-poor households	<i>Structural poverty</i>	<i>Socially integrated</i>

Source: Adapted from Feres and Mancero (2001).

III.3. Economic Polarization and Ethnicity

A last but not minor aspect of the situation of Chilean indigenous has to do with the concept of polarization, firstly formalized by Esteban and Ray (ER) (1994) and Wolfson (1994). The concept of polarization in Economics relates to the extent that, given an income distribution, population is clustered around a small number of distant poles. The interesting feature behind this idea is that a polarized society is more likely to suffer social tensions and conflicts. Formally, ER defines polarization as the sum of antagonisms between individuals that belong to different groups, that is,

$$ER(\alpha) = \sum_{i=1}^k \sum_{j=1}^k p_i^{1+\alpha} p_j |\bar{y}_i - \bar{y}_j|; 1 \leq \alpha \leq 1.6$$

where \bar{y}_i denotes the mean income (in logs) of group i , p_i represents the share of population represented by group i and α is a parameter capturing the polarization aversion.

⁶ For details on more complex methodologies see, for example, Boltvitnik (2003).

ER formalization of polarization can be applied to income classes, but also to categorical variables, like ethnicity. Other authors (and Esteban and Ray themselves) have proposed variations of this measure. Among these other index of measurement, we make use of the one defined by Zhang and Kanbur (ZK) (2001), which, according to the authors, is able to provide an approach to polarization less linked to inequality and it is especially conceived to deal with categorical variables (regions, races, etc.). The ZK measure can be expressed as the ratio of between-group generalized entropy inequality to within-group generalized entropy measure. The most frequent choice –also followed here- is to make use of the Theil index, so this polarization measure can be formally written in the following form:

$$ZK = \frac{T_b}{T_w} = \frac{\frac{1}{K} \sum_{i=1}^K \ln \frac{\bar{y}}{y_i}}{\frac{1}{K} \sum_{i=1}^K T_i} \text{ where } T_i = \frac{1}{n_i} \sum_{h \in i} \ln \frac{\bar{y}_i}{y_h}$$

where T_b and T_w are the between-group and within-group Theil index, respectively. T_i denotes the Theil index computed for group i .⁷

All calculations are performed using Stata 10 and programs are available from the authors upon request.

⁷ Note that we are using the Theil index with inequality aversion factor equal to zero. An alternative formulation of the Theil index is the generalized entropy measure with factor equal to one.

IV. Results

IV.1. Poverty

Results from the poverty analysis using the tools described above are presented in figures 2-5. While figures 2 and 3 describe the main trends in terms of absolute poverty, figure 4 reproduces poverty figures when using on a relative concept of monetary deprivation according to the rules stated in section 3. Since indigenous population represents a low share of total population (roughly 5%), we only present estimates for indigenous and non-indigenous people, as estimates for total population are quite similar to non-indigenous ones. Nevertheless, this information is available from the authors upon request.

Figure 1 shows the evolution of extreme poverty among both indigenous and non-indigenous population. At the end of the period, we can see that the incidence, intensity and severity of indigence were lower at the end of the period. This specially applies to the poverty gap and the squared poverty gap.

Trends in moderate poverty are depicted by figure 2. It is quite remarkable that poverty reduction is much more intense among both groups than in the case of indigence, which is verified for the incidence, intensity and severity of poverty risk. For instance, more than 40% of indigenous population were at poverty risk in 1996, while this share was around 20% ten years later.

Particularly, it is interesting to compute the growth elasticity of poverty by ethnicity along the decade. This can be done simply using the following expression:

$$\varepsilon = \frac{\% \Delta \text{Poverty}}{\% \Delta \text{Per capita income}}$$

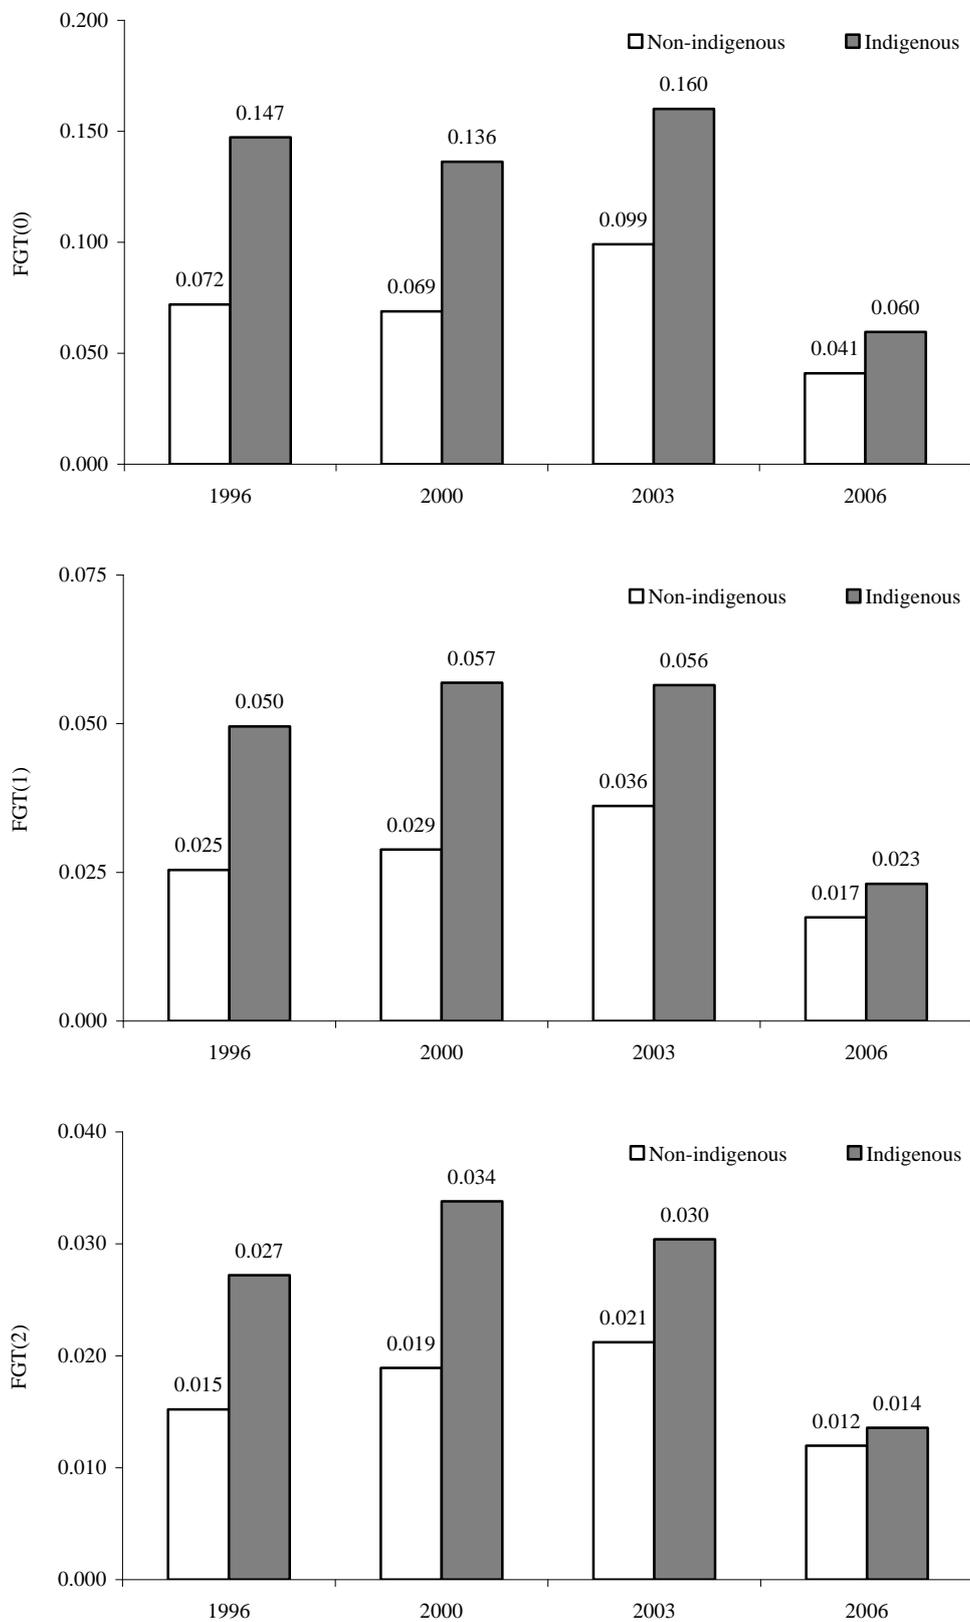

While the growth-elasticity of non-indigenous poverty was -in absolute value- 2.45, the elasticity for indigenous groups was higher, 2.82, indicating that a 1% increase in per capita income reduces the incidence of absolute moderate poverty by almost 3% among aborigines.⁸

⁸ In order to compute elasticities we had to index per capita income from 1996 using the consumer price index calculated by the Central Bank of Chile. (www.bcentral.cl).

Figure 2. Moderate poverty among indigenous and non-indigenous in Chile (1996-2006)

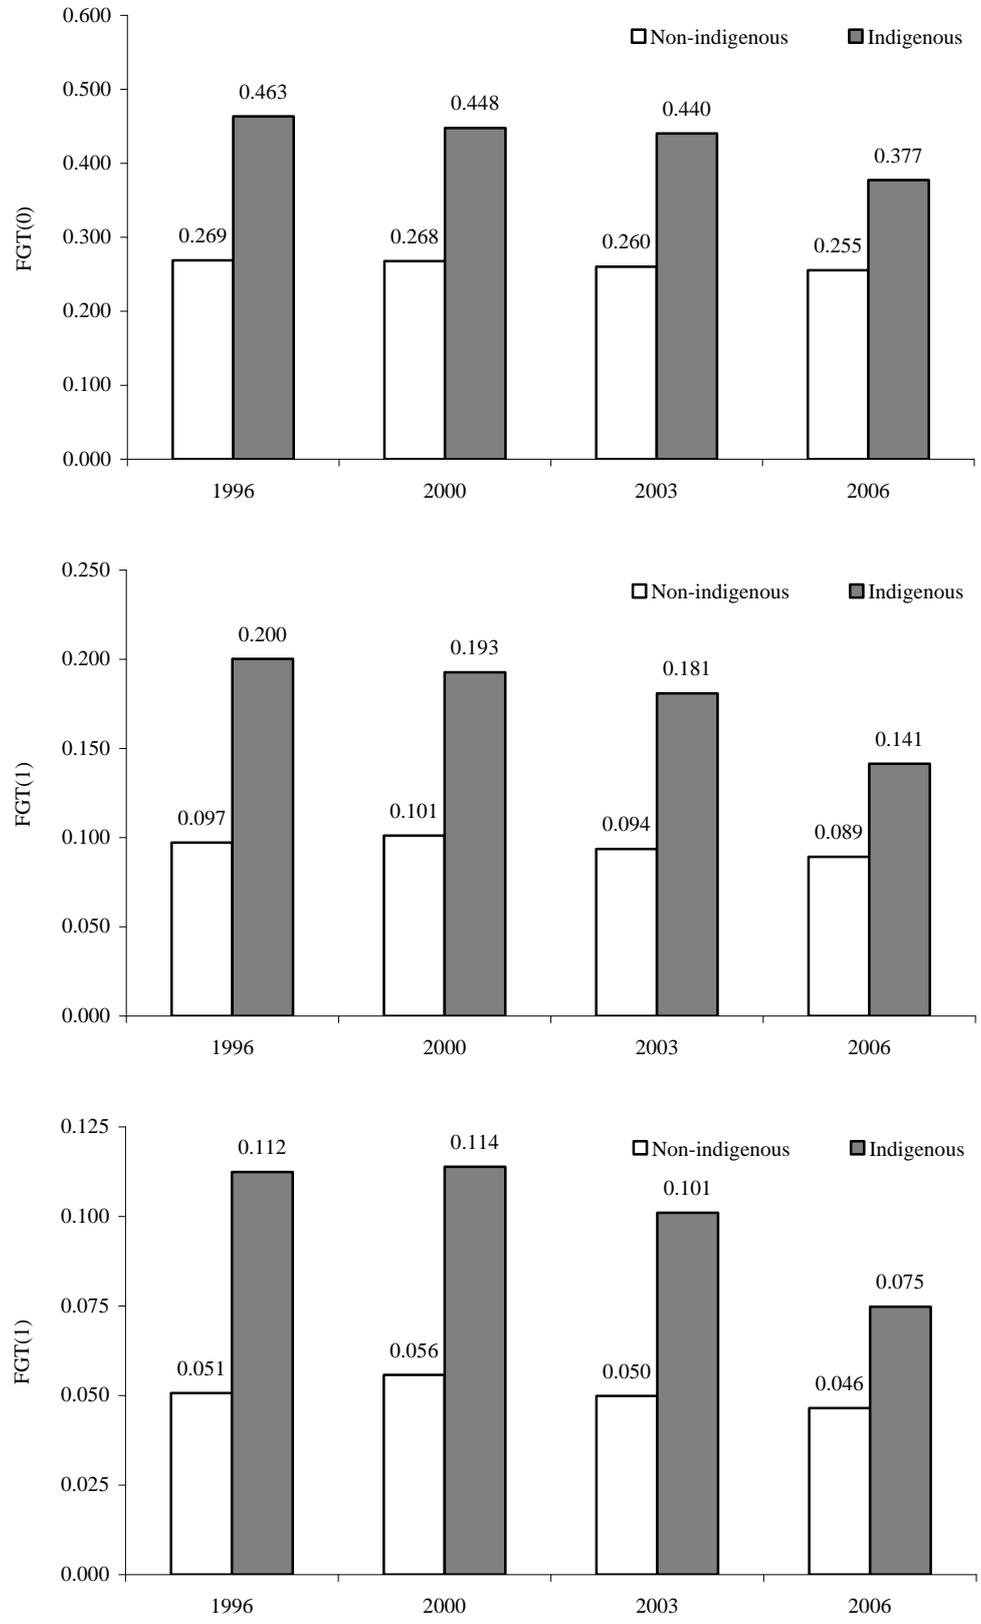

Source: Authors' analysis from CASEN micro-data.

The last issue to address in our analysis of monetary deprivation has to do with relative poverty. This measure considers that the minimum life standards are socially constructed, depending therefore on the affluence of the society where you live. As Chile has experienced an economic boost along the period 1996-2006, so does the relative poverty line (60% of the median). Figure 3 shows that, unlike non-indigenous population, the progress of indigenous population in terms of relative poverty has been remarkable according to the three FGT indexes considered. For example, while poverty incidence among non-indigenous passed from 26.9 to 25.5%, poverty risk among indigenous groups decreased by roughly 9 points. What can be behind this trend? One should bear in mind that the use a relative measure of poverty is quite like accounting for inequality. It is well-known that inequality in Chile did not experience huge variations during the last years, so it is understandable that relative deprivation among non-indigenous (which accounts for more than 90% of population) did not diminish very much. Nevertheless, the trend in indigenous poverty shows that the improvement of economic position of this group was not only absolute but also relative to the bottom of the income distribution. This can be also confirmed by looking at the distribution of indigenous by deciles of disposable income (figure 4).

IV.2. Unsatisfied basic needs

In an attempt of capturing some other dimensions of poverty apart from the purely monetary one, following the guidelines presented above, this subsection computes the proportion of people by ethnic group living with any kind of basic need. As mentioned, four different dimensions are considered: dwelling quality, water and sewerage, children education and subsistence capacity.

Figure 5 reproduces the proportion of both indigenous and non-indigenous population living in households with each type of unsatisfied basic need. Two stylized facts can be highlighted. First, in all dimensions considered, indigenous population present worse indicators than non-indigenous individuals. Second, the access to adequate water and sewerage and the subsistence capacity of households has substantially improved along the decade 1996-2006. In addition, school attendance among young children is nearly universal, as the proportion of people living in households presenting this feature is negligible in 2006 among both collectives. Regarding dwelling, it is particularly interesting that no substantial improvement neither among indigenous nor non-indigenous population has taken place. There is even a slight increase of non-indigenous individuals living in crowded households

or low-quality dwellings. In the light of the evident improvement observed in other indicators, this trend seems at least controversial. At this respect, it is worthy mentioning that this indicator is built on the basis of questions whose answer is provided by the interviewer according to some guidelines provided by the Ministry.⁹ If one goes into detail, this trend can be basically explained by a worse state of walls, floors and roofs according to interviewers' reports. Anyway, it seems quite clear that the improvement observed in the remaining indicators is not a feature characterising the evolution of dwelling quality, which proves to some extent the importance of adopting a multidimensional approach to poverty.¹⁰

Figure 6 presents a simple aggregation of the different UBN, showing what proportion of people had any UBN or two or more UBN along the analysed period. Data are in line with the trends described in the above paragraph: indigenous suffer a higher deprivation according to both indicators and the share of people experiencing deprivation substantially diminished from 1996 to 2006.

Figure 7 tries to determine to what extent indigenous people has seen their deprivation reduced compared with the rest of Chilean population. During the analysed period, with the exception of water and sewerage, a dimension where non-indigenous experienced a larger improvement, and the proportion of people with two or more UBN, which present a similar reduction among both groups, we find more substantial improvements among indigenous than among the rest of Chileans. However, as shown in figure 5, one should bear in mind that the absolute gap in all dimensions is persistent and non-negligible.

The final step in the analysis of multidimensional deprivation is to combine our non-monetary indicators with those purely derived from household income. The picture described by the integrated method of poverty measurement presented in the previous section is reproduced by figure 8. Particularly, we have used only the moderate poverty line (computed from the absolute perspective of measurement). The results obtained using this approach are not very different from those presented above: the most severe states of deprivation (i.e., chronic and structural poverty) are much more acute among indigenous.

⁹ For 2006, see the Interviewer Manual (Mideplan, 2006). However, as long as interviewers can change over time and the application of the criteria about the state of materials may be seen as quite flexible and subjective, this result can be affected by some bias of respondents.

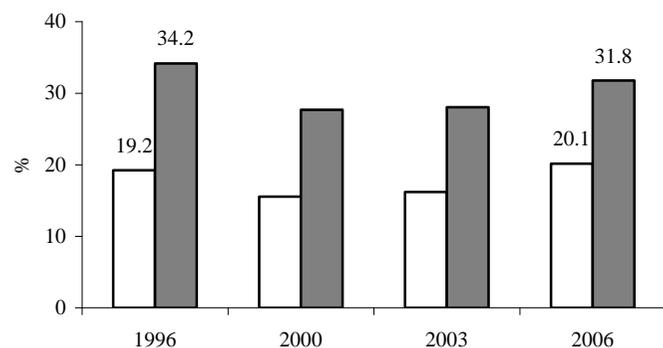

¹⁰ It is possible that, in order to improve dwelling (a duration good), a long period of growth or/and access to financial markets are required.

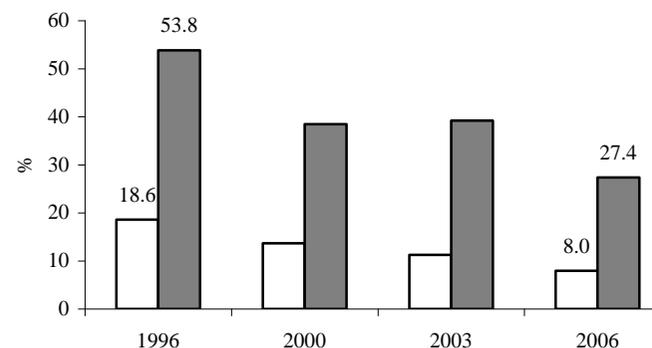

However, from 1996 to 2006 there were large improvements in social indicators for both groups, with a better performance of indigenous regarding structural poverty. One important lesson that can be drawn from this analysis is that the diminution of deprivation in both groups is much smaller than using only poverty lines methods, though the reduction of the acutest form of material shortage (chronic poverty) was undoubtedly significant.

IV.3. Polarization

This empirical analysis concludes exploring the degree of polarization among ethnic groups observed in Chile, a concept that has to do with the degree of antagonism observed between indigenous groups and the rest of population in terms of income. We make use of the two measures of polarization described in the previous section.¹¹ The results of this analysis are showed in figure 9. As can be seen, both measures show that there was a slight increase of antagonism between indigenous and non-indigenous in Chile during the period 1996-2006. However, these levels are remarkably low compared with the polarization observed between “rich” and “poor”, that is, between the half of total population with an income level below the median and the other half whose income is above that threshold, which are 0.656 and 1.420 in 2006 according to ER and ZK measures, respectively. In order to refine our assessment of economic polarization by ethnicity, we recalculate the index considering only those regions with a proportion of indigenous population above 20% (Regions I, II, IX, X and XII). Surprisingly, though polarization is now higher, the (slightly) increasing trend vanishes. Therefore, it is not possible to link polarization to the emergence of conflicts and violence episodes in those regions. It is possible that other kinds of polarizations out from the scope of this article (in terms of wealth or land or even ethnic fragmentation itself or economic polarization computed at a lower level, for instance, at village level) might be relevant.

¹¹ For reasons of space, regarding the Esteban-Ray index, we only reports *the results obtained when a -the polarization aversion parameter- equals 1.3*. Other values between 1 and 1.6 yield similar results.

V. Conclusions

The so called “Indigenous question” has been receiving increasing attention in Latin America during the last decade. However, Chile, the country with the best economic performance during that period, seems to have been a remarkable exception, as few studies have addressed the social and economic situation of aborigines. To our knowledge, this study is the first one in analysing social deprivation among indigenous groups in a systematic way. Our findings point out several interesting facts.

First, indigenous in Chile has experienced and continue suffering clearly higher levels of both monetary and non-monetary deprivation than non-indigenous population.

Second, income polarization by ethnicity does not seem very important, showing non-increasing levels, especially when comparing with polarization by income groups.

Third, on the basis of our findings, it cannot be argued that indigenous have been excluded from the economic prosperity experienced by the country along the decade 1996-2006. On the contrary, most of our indicators point out that indigenous population have benefited from larger improvements in living conditions during such period.
